# Intro: Oregon Health Insurance Experiment

In 2008, Oregon gave access to socialised health insurance by wait-list lottery.

Mean Outcome, for each  $z' = 0, 1$ .

**Applied practice:**

⇒ Suggestive evidence for healthcare as mechanism for wait-list lottery. . . .

# Intro: Oregon Health Insurance Experiment

In 2008, Oregon gave access to socialised health insurance by wait-list lottery (Finkelstein et al, 2012).

**Figure:** Model for Suggestive Evidence of a Mechanism.

---

## Inconsistencies in suggestive evidence of mechanisms:

- Is  $D_i \rightarrow Y_i$  small, large, or even existent?
- Where else do we accept assumed causal effects without evidence?

# Introduction — Contributions

Causal Mediation (CM) is an alternative framework to studying mechanisms, with clear identification and assumptions required.

---

- ① Problems with conventional approach to CM in observational settings.  
[Negative result]
  - ② Recovering valid CM effects, via MTE + control function modelling.  
[Positive result]
- 

New insights from intersection of two fields:

- **Causal Mediation (CM).**

Imai Keele Yamamoto (2010), Frölich Huber (2017), Deuchert Huber Schelker (2019), Huber (2020), Kwon Roth (2024).

- **Labour theory, Selection-into-treatment, MTEs.**

Roy (1951), Heckman (1979), Heckman Honoré (1990), Vycatil (2002), Heckman Vycatil (2005), Brinch Mogstad Wiswall (2017), Kline Walters (2019).

# Introduction – CM

Consider ignorable **treatment**  $Z_i = 0, 1$ , binary **mediator**  $D_i = 0, 1$ , and continuous **outcome**  $Y_i$ .

---

Assumption: **Mediator Ignorability** (MI, Imai Keele Yamamoto 2010)  
mediator  $D_i$  is *also* ignorable, conditional on  $X_i$  and  $Z_i$  realisation.

---

Average Direct Effect (ADE) and Average Indirect Effect (AIE) are identified by two-stage regression

- ADE is causal effect  $Z_i \rightarrow Y_i$ , blocking the indirect  $D_i$  path
- AIE is causal effect of  $D_i(Z_i) \rightarrow Y_i$ , blocking the direct  $Z_i$  path.

# Introduction – CM

Consider ignorable **treatment**  $Z_i = 0, 1$ , binary **mediator**  $D_i = 0, 1$ , and continuous **outcome**  $Y_i$ .

---

Assumption: **Mediator Ignorability** (MI, Imai Keele Yamamoto 2010)  
mediator  $D_i$  is *also* ignorable, conditional on  $X_i$  and  $Z_i$  realisation.

---

Average Direct Effect (ADE) and Average Indirect Effect (AIE) are identified by two-stage regression

- ADE is causal effect  $Z_i \rightarrow Y_i$ , blocking the indirect  $D_i$  path
- AIE is causal effect of  $D_i(Z_i) \rightarrow Y_i$ , blocking the direct  $Z_i$  path.

# Introduction – CM

Consider ignorable **treatment**  $Z_i = 0, 1$ , binary **mediator**  $D_i = 0, 1$ , and continuous **outcome**  $Y_i$ .

---

Assumption: **Mediator Ignorability** (MI, Imai Keele Yamamoto 2010)  
**mediator**  $D_i$  is *also* ignorable, conditional on  $\mathbf{X}_i$  and  $Z_i$  **realisation**.

---

Average Direct Effect (ADE) and Average Indirect Effect (AIE) are identified by two-stage regression

- ADE is causal effect  $Z_i \rightarrow Y_i$ , blocking the indirect  $D_i$  path
- AIE is causal effect of  $D_i(Z_i) \rightarrow Y_i$ , blocking the direct  $Z_i$  path.

# 1. Selection Bias

Assumption: **Mediator ignorability (MI, Imai Keele Yamamoto 2010)**

mediator  $D_i$  is *also* ignorable, conditional on  $X_i$ ,  $Z_i$  realisation

Would this assumption hold true in settings economists study?

E.g., Oregon Health Insurance Experiment.

- 1 Treatment is as-good-as random (2008 Oregon wait-list lottery).
- 2 Healthcare is quasi-random, conditional on lottery realisation  $Z_i$  and demographic controls  $X_i$ .

# 1. Selection Bias

Assumption: **Mediator ignorability (MI)**, Imai Keele Yamamoto 2010)

mediator  $D_i$  is *also* ignorable, conditional on  $X_i$ ,  $Z_i$  realisation

Would this assumption hold true in settings economists study?

E.g., Oregon Health Insurance Experiment.

**Theorem:** If choice to attend healthcare is unconstrained, based on costs and benefits (Roy model) and demographics do not explain all benefits  $\implies$  **MI** does not hold, there is unobserved confounding.

# 1. Selection Bias

Assumption: **Mediator ignorability (MI)**, Imai Keele Yamamoto 2010)

mediator  $D_i$  is *also* ignorable, conditional on  $X_i$ ,  $Z_i$  realisation

Would this assumption hold true in settings economists study?

E.g., Oregon Health Insurance Experiment.

**Theorem:** If choice to attend healthcare is unconstrained, based on costs and benefits (Roy model) and demographics do not explain all benefits  $\implies$  **MI** does not hold, there is unobserved confounding.

# 1. Selection Bias

In an observational setting, need an additional credible research design for **Mediator Ignorability (MI)** to be credible.

If not, then CM effects are contaminated by bias terms, similar to classical selection bias (e.g., Heckman Ichimura Smith Todd 1998).

- ADE: CM Estimand = ADE + (Selection Bias + Group difference bias)
- AIE: CM Estimand = AIE + (Selection Bias + Group difference bias)

► ADE biases

► AIE biases

# 1. Selection Bias

In an observational setting, need an additional credible research design for **Mediator Ignorability (MI)** to be credible.

If not, then CM effects are contaminated by bias terms, similar to classical selection bias (e.g., Heckman Ichimura Smith Todd 1998).

- ADE: CM Estimand = ADE + (Selection Bias + Group difference bias)
- AIE: CM Estimand = AIE + (Selection Bias + Group difference bias)

► ADE biases

► AIE biases

# 1. Selection Bias

In a simulation with Roy selection-into- $D_i$ , CM estimates are biased.

(a)  $\widehat{ADE} - ADE$ .

(b)  $\widehat{AIE} - AIE$ .

## 2. CM with Selection

Conventional CM methods do not identify  $ADE + AIE$  in a natural experiment setting, but can we build a credible structural model?

Suppose  $Z_i$  is ignorable, but  $D_i$  is not:

- 1 Average first-stage,  $Z_i \rightarrow D_i$ , is identified
- 2 Average second-stage,  $Z_i, D_i \rightarrow Y_i$ , is not — represented by  $U_i$ .

**Intuition:** model  $U_i$  via mediator MTE to identify  $ADE + AIE$ .

## 2. CM with Selection — Identification

- MTE assumptions:
- 1 Mediator monotonicity
  - 2 Selection on mediator benefits
  - 3 IV for mediator take-up cost.

Causal model:

**Proposition:** Under MTE assumptions, the mediator MTE is identified.

**Theorem:** Mediation second-stage effects,  $Z_i, D_i \rightarrow Y_i$ , are identified by the MTE associated Control Functions (CFs).

## 2. CM with Selection — Identification

- MTE assumptions:
- 1 Mediator monotonicity
  - 2 Selection on mediator benefits
  - 3 IV for mediator take-up cost.

Causal model:

**Proposition:** Under MTE assumptions, the mediator MTE is identified.

**Theorem:** Mediation second-stage effects,  $Z_i, D_i \rightarrow Y_i$ , are identified by the MTE associated Control Functions (CFs).

## 2. CM with Selection — Identification

- MTE assumptions:
- 1 Mediator monotonicity
  - 2 Selection on mediator benefits
  - 3 IV for mediator take-up cost.

Causal model:

**Proposition:** Under MTE assumptions, the mediator MTE is identified.

**Theorem:** Mediation second-stage effects,  $Z_i, D_i \rightarrow Y_i$ , are identified by the MTE associated Control Functions (CFs).

## 2. CM with Selection — Identification

- MTE assumptions:
- 1 Mediator monotonicity
  - 2 Selection on mediator benefits
  - 3 IV for mediator take-up cost.

Causal model:

**Proposition:** Under MTE assumptions, the mediator MTE is identified.

**Theorem:** Mediation second-stage effects,  $Z_i, D_i \rightarrow Y_i$ , are identified by the MTE associated Control Functions (CFs).

## 2. CM with Selection — Identification

- MTE assumptions:
- 1 Mediator monotonicity
  - 2 Selection on mediator benefits
  - 3 IV for mediator take-up cost.

Causal model:

**Proposition:** Under MTE assumptions, the mediator MTE is identified.

**Theorem:** Mediation second-stage effects,  $Z_i, D_i \rightarrow Y_i$ , are identified by the MTE associated Control Functions (CFs).

## 2. CM with Selection — Identification

- MTE assumptions:
- 1 Mediator monotonicity
  - 2 Selection on mediator benefits
  - 3 IV for mediator take-up cost.

Causal model:

**Proposition:** Under MTE assumptions, the mediator MTE is identified.

**Intuition:** Identifies ADE + AIE by extrapolating from IV compliers to mediator compliers (MTE extrapolation e.g., Mogstad Torgovitsky 2018).

## 2. CM with Selection — Identification

- MTE assumptions:
- 1 Mediator monotonicity
  - 2 Selection on mediator benefits
  - 3 IV for mediator take-up cost.

Causal model:

**Proposition:** Under MTE assumptions, the mediator MTE is identified.

**Intuition:** Identifies ADE + AIE by extrapolating from IV compliers to mediator compliers (MTE extrapolation e.g., Mogstad Torgovitsky 2018).

## 2. CM with Selection — Estimation

In practice, this means two-stage CM estimation, with CF in second-stage.

---

### Parametric CF Estimation Recipe:

- 1 Estimate mediation first-stage with probit, including the IV.
- 2 Estimate mediation second-stage by OLS, with Mills ratio CF terms (Heckman 1979).
- 3 Compose CM estimates from two-stage plug-in estimates (same as parametric MTEs, Björklund Moffitt 1987).

### Semi-parametric CF Estimation Recipe:

Replace 2. with semi-parametric CFs (same estimation as MTEs).

---

⇒ Conventional CM estimates (two-stages) + IV-guided CF adjustment.

## 2. CM with Selection — Estimation

**Figure:** CM Estimates from 10,000 DGPs with **Normal** Errors.

(a)  $\widehat{ADE} - ADE$ .

Density

(b)  $\widehat{AIE} - AIE$ .

Density

## 2. CM with Selection — Estimation

In practice, this means two-stage CM estimation, with CF in second-stage.

---

### Parametric CF Estimation Recipe:

- 1 Estimate mediation first-stage with probit, including the IV.
- 2 Estimate mediation second-stage by OLS, with Mills ratio CF terms (Heckman 1979).
- 3 Compose CM estimates from two-stage plug-in estimates (same as parametric MTEs, Björklund Moffitt 1987).

### Semi-parametric CF Estimation Recipe:

Replace 2. with semi-parametric CFs (same estimation as MTEs).

---

⇒ Conventional CM estimates (two-stages) + IV-guided CF adjustment.

## 2. CM with Selection — Estimation

In practice, this means two-stage CM estimation, with CF in second-stage.

---

### Parametric CF Estimation Recipe:

- 1 Estimate mediation first-stage with probit, including the IV.
- 2 Estimate mediation second-stage by OLS, with Mills ratio CF terms (Heckman 1979).
- 3 Compose CM estimates from two-stage plug-in estimates (same as parametric MTEs, Björklund Moffitt 1987).

### Semi-parametric CF Estimation Recipe:

Replace 2. with semi-parametric CFs (same estimation as MTEs).

---

⇒ Conventional CM estimates (two-stages) + IV-guided CF adjustment.

Density

### 3. Returning to Oregon

Winning access to Medicaid increases healthcare usage, and subjective health:

CM is quantitatively estimating the entire system:

- Use correlational estimate of  $D_i \rightarrow Y_i$
- Does visiting healthcare at least once increase subjective health 12 months later?
- OLS for  $D_i \rightarrow Y_i$  is  $\approx 0$  (not significant).

### 3. Returning to Oregon

Winning access to Medicaid increases healthcare usage, and subjective health:

CM is quantitatively estimating the entire system:

- Use correlational estimate of  $D_i \rightarrow Y_i$
- Does visiting healthcare at least once increase subjective health 12 months later?
- OLS for  $D_i \rightarrow Y_i$  is  $\approx 0$  (not significant).

### 3. Returning to Oregon

Winning access to Medicaid increases healthcare usage, and subjective health:

CM is quantitatively estimating the entire system:

- Use correlational estimate of  $D_i \rightarrow Y_i$
- Does visiting healthcare at least once increase subjective health 12 months later?
- OLS for  $D_i \rightarrow Y_i$  is  $\approx 0$  (not significant).

### 3. Returning to Oregon

Conventional CM estimates lottery effects as mostly direct,  $\approx 0$  healthcare.

Estimate, percent effect on subjective health

### 3. Returning to Oregon

Winning access to Medicaid increases healthcare usage, and subjective health:

My approach to CM is modelling selection-into- $D_i$  via mediator MTE:

- Uses an estimate of  $D_i \rightarrow Y_i$  (plus complier extrapolation)
- Regular healthcare location pre-lottery serves as first-stage IV IV.
- IV + CF extrapolation estimates of  $D_i \rightarrow Y_i$  are larger  
 $\implies$  smaller ADE estimates.

### 3. Returning to Oregon

Winning access to Medicaid increases healthcare usage, and subjective health:

My approach to CM is modelling selection-into- $D_i$  via mediator MTE:

- Uses an estimate of  $D_i \rightarrow Y_i$  (plus complier extrapolation)
- Regular healthcare location pre-lottery serves as first-stage IV IV.
- IV + CF extrapolation estimates of  $D_i \rightarrow Y_i$  are larger  
     $\Rightarrow$  smaller ADE estimates.

### 3. Returning to Oregon

Winning access to Medicaid increases healthcare usage, and subjective health:

My approach to CM is modelling selection-into- $D_i$  via mediator MTE:

- Uses an estimate of  $D_i \rightarrow Y_i$  (plus complier extrapolation)
- Regular healthcare location pre-lottery serves as first-stage IV ▶ IV.
- IV + CF extrapolation estimates of  $D_i \rightarrow Y_i$  are larger  
     $\implies$  smaller ADE estimates.

### 3. Returning to Oregon

Using my approach, with regular healthcare location as an excluded IV, restores indirect effect through increasing healthcare visitation.

Estimate, percent effect on subjective health

# Conclusion

## Overview:

- ① CM as alternative to “suggestive evidence for mechanisms.”
- ② Selection bias in conventional CM analyses with no case for mediator ignorability.
- ③ Connect CM with labour theory + selection-into-treatment + MTEs.

---

## Caveats and points to remember:

- Structural assumptions and IV for identification + estimation (not ideal).
- Application to Oregon Health Insurance Experiment, showing subjective health + well-being effects mediated by healthcare.
- **Credible** analyses of mechanisms are hard in practice, wide confidence intervals show true uncertainty.

## Appendix: CM Guiding Model

Consider binary **treatment**  $Z_i = 0, 1$ , binary **mediator**  $D_i = 0, 1$ , and continuous **outcome**  $Y_i$ .

Average Direct Effect (ADE):  $\mathbb{E} \left[ Y_i \left( \mathbf{1}, D_i(Z_i) \right) - Y_i \left( \mathbf{0}, D_i(Z_i) \right) \right]$

- ADE is causal effect  $Z \rightarrow Y$ , blocking the indirect  $D_i$  path.

Average Indirect Effect (AIE):  $\mathbb{E} \left[ Y_i \left( Z_i, \mathbf{D_i(1)} \right) - Y_i \left( Z_i, \mathbf{D_i(0)} \right) \right]$

- AIE is causal effect of  $D_i(Z_i) \rightarrow Y_i$ , blocking the direct  $Z_i$  path.

# Group Difference — ADE

CM effects contaminated by (less interpretable) bias terms.

$$\text{CM Estimand} = \text{ADEM} + \text{Selection Bias}$$

$$\begin{aligned} & \underbrace{\mathbb{E}_{D_i} \left[ \mathbb{E} [Y_i \mid Z_i = 1, D_i] - \mathbb{E} [Y_i \mid Z_i = 0, D_i] \right]}_{\text{Estimand, Direct Effect}} \\ &= \underbrace{\mathbb{E}_{D_i=d'} \left[ \mathbb{E} [Y_i(1, D_i(Z_i)) - Y_i(0, D_i(Z_i)) \mid D_i(1) = d'] \right]}_{\text{Average Direct Effect on Mediator (ADEM) take-up — i.e., } D_i(1) \text{ weighted}} \\ & \quad + \underbrace{\mathbb{E}_{D_i} \left[ \mathbb{E} [Y_i(0, D_i(Z_i)) \mid D_i(1) = d'] - \mathbb{E} [Y_i(0, D_i(Z_i)) \mid D_i(0) = d'] \right]}_{\text{Selection Bias}} \end{aligned}$$

The weighted ADE you get here is a positive weighted sum of local ADEs, but with policy irrelevant weights  $D_i(1) = d'$ .

⇒ consider this group bias, noting difference from true ADE. [▶ Back](#)

# Selection Bias — Direct Effect

CM Effects + contaminating bias.

$$\text{CM Estimand} = \text{ADE} + \left( \text{Selection Bias} + \text{Group difference bias} \right)$$

► Model

$$\begin{aligned} & \underbrace{\mathbb{E}_{D_i=d'} \left[ \mathbb{E} [Y_i \mid Z_i = 1, D_i = d'] - \mathbb{E} [Y_i \mid Z_i = 0, D_i = d'] \right]}_{\text{Estimand, Direct Effect}} \\ &= \underbrace{\mathbb{E} [Y_i(1, D_i(Z_i)) - Y_i(0, D_i(Z_i))]}_{\text{Average Direct Effect}} \\ &+ \underbrace{\mathbb{E}_{D_i=d'} \left[ \mathbb{E} [Y_i(0, D_i(Z_i)) \mid D_i(1) = d'] - \mathbb{E} [Y_i(0, D_i(Z_i)) \mid D_i(0) = d'] \right]}_{\text{Selection Bias}} \\ &+ \underbrace{\mathbb{E}_{D_i=d'} \left[ \left( 1 - \Pr(D_i(1) = d') \right) \right.}_{\text{Group difference bias}} \\ &\quad \times \left. \left( \mathbb{E} [Y_i(1, D_i(Z_i)) - Y_i(0, D_i(Z_i)) \mid D_i(1) = 1 - d'] \right. \right. \\ &\quad \left. \left. - \mathbb{E} [Y_i(1, D_i(Z_i)) - Y_i(0, D_i(Z_i)) \mid D_i(0) = d'] \right) \right]}_{\text{Group-diff}} \end{aligned}$$

# Group Difference — AIE

CM effects contaminated by (less interpretable) bias terms.

$$\text{CM Estimand} = \text{AIEM} + \left( \text{Selection Bias} + \text{Group difference bias} \right)$$

$$\begin{aligned} & \underbrace{\mathbb{E}_{Z_i} \left[ \left( \mathbb{E}[D_i | Z_i = 1] - \mathbb{E}[D_i | Z_i = 0] \right) \times \left( \mathbb{E}[Y_i | Z_i, D_i = 1] - \mathbb{E}[Y_i | Z_i, D_i = 0] \right) \right]}_{\text{Estimand, Indirect Effect}} \\ &= \underbrace{\mathbb{E} \left[ Y_i(Z_i, D_i(1)) - Y_i(Z_i, D_i(0)) \mid D_i = 1 \right]}_{\text{Average Indirect Effect on Mediated (AIEM) — i.e., } D_i = 1 \text{ weighted}} \\ &+ \underbrace{\pi \left( \mathbb{E}[Y_i(Z_i, 0) \mid D_i = 1] - \mathbb{E}[Y_i(Z_i, 0) \mid D_i = 0] \right)}_{\text{Selection Bias}} \\ &+ \underbrace{\pi \left[ \left( \frac{1 - \Pr(D_i(1) = 1, D_i(0) = 0)}{\Pr(D_i(1) = 1, D_i(0) = 0)} \right) \left( \mathbb{E}[Y_i(Z_i, 1) - Y_i(Z_i, 0) \mid D_i(1) = 0 \text{ or } D_i(0) = 1] - \mathbb{E}[Y_i(Z_i, 1) - Y_i(Z_i, 0)] \right) \right]}_{\text{Groups difference Bias}} \end{aligned}$$

The weighted AIE you get here is not a positive weighted sum of local AIEs, because the AIE is only about  $D(Z)$  compliers. [► Model](#).

⇒ consider this group bias, noting difference from true AIE. [► Back](#)

# Selection Bias — Indirect Effect

CM Effects + contaminating bias, where  $\bar{\pi} = \Pr(D_i(0) \neq D_i(1))$ .

$$\text{CM Estimand} = \text{AIE} + \left( \text{Selection Bias} + \text{Group difference bias} \right) \quad \text{► Model}$$

$$\begin{aligned} & \underbrace{\mathbb{E}_{Z_i} \left[ \left( \mathbb{E}[D_i | Z_i = 1] - \mathbb{E}[D_i | Z_i = 0] \right) \times \left( \mathbb{E}[Y_i | Z_i, D_i = 1] - \mathbb{E}[Y_i | Z_i, D_i = 0] \right) \right]}_{\text{Estimand, Indirect Effect}} \\ &= \underbrace{\mathbb{E}[Y_i(Z_i, D_i(1)) - Y_i(Z_i, D_i(0))]}_{\text{Average Indirect Effect}} \\ &+ \underbrace{\bar{\pi} \left( \mathbb{E}[Y_i(Z_i, 0) | D_i = 1] - \mathbb{E}[Y_i(Z_i, 0) | D_i = 0] \right)}_{\text{Selection Bias}} \\ &+ \bar{\pi} \left[ \begin{aligned} & \left( 1 - \Pr(D_i = 1) \right) \left( \mathbb{E}[Y_i(Z_i, 1) - Y_i(Z_i, 0) | D_i = 1] \right. \\ & \quad \left. - \mathbb{E}[Y_i(Z_i, 1) - Y_i(Z_i, 0) | D_i = 0] \right) \\ & + \left( \frac{1 - \Pr(D_i(1) = 1, D_i(0) = 0)}{\Pr(D_i(1) = 1, D_i(0) = 0)} \right) \left( \mathbb{E}[Y_i(Z_i, 1) - Y_i(Z_i, 0) | D_i(Z_i) \neq Z_i] \right. \\ & \quad \left. - \mathbb{E}[Y_i(Z_i, 1) - Y_i(Z_i, 0)] \right) \end{aligned} \right] \end{aligned}$$

Groups difference Bias    ► Group-diff

# Semi-parametric Control Functions

Semi-parametric specifications for the CFs  $\lambda_0, \lambda_1$  bring some complications to estimating the AIE.

$$\mathbb{E}[Y_i | Z_i, D_i = 0, \mathbf{X}_i] = \alpha + \gamma Z_i + \varphi(\mathbf{X}_i) + \rho_0 \lambda_0(\pi(Z_i; \mathbf{X}_i)),$$

$$\mathbb{E}[Y_i | Z_i, D_i = 1, \mathbf{X}_i] = (\alpha + \beta) + (\gamma + \delta) Z_i + \varphi(\mathbf{X}_i) + \rho_1 \lambda_1(\pi(Z_i; \mathbf{X}_i))$$

Intercepts,  $\alpha, (\alpha + \beta)$ , and relevance parameters  $\rho_0, \rho_1$  are not separately identified from the CFs  $\lambda_0(\cdot), \lambda_1(\cdot)$  so CF extrapolation term  $(\rho_1 - \rho_0)\Gamma(\pi(0; \mathbf{X}_i), \pi(1; \mathbf{X}_i))$  is not directly identified or estimable.

These problems can be avoided by estimating the AIE using its relation to the ATE,  $\widehat{\text{AIE}}^{\text{CF}} =$

$$\widehat{\text{ATE}} - (1 - \bar{Z}) \underbrace{\left( \frac{1}{N} \sum_{i=1}^N \hat{\gamma} + \hat{\delta} \hat{\pi}(1; \mathbf{X}_i) \right)}_{\widehat{\text{ADE}} \text{ given } Z_i=1} - \bar{Z} \underbrace{\left( \frac{1}{N} \sum_{i=1}^N \hat{\gamma} + \hat{\delta} \hat{\pi}(0; \mathbf{X}_i) \right)}_{\widehat{\text{ADE}} \text{ given } Z_i=0}.$$

## Appendix: CM with Selection

Suppose  $Z_i$  is ignorable,  $D_i$  is not, so we have the following causal model.

Then this system has the following random coefficient equations:

$$D_i = \phi + \pi Z_i + \varphi(\mathbf{X}_i) + U_i$$

$$Y_i = \alpha + \beta D_i + \gamma Z_i + \delta Z_i D_i + \zeta(\mathbf{X}_i) + \underbrace{(1 - D_i) U_{0,i} + D_i U_{1,i}}_{\text{Correlated error term}}$$

where  $\beta, \gamma, \delta$  are functions of  $\mu_{d'}(z'; \mathbf{X}_i)$ .

$$\text{ADE} = \mathbb{E}[\gamma + \delta D_i], \quad \text{AIE} = \mathbb{E}\left[\pi(\beta + \delta Z_i + \tilde{U}_i)\right]$$

with  $\tilde{U}_i = \mathbb{E}[U_{1,i} - U_{0,i} | \mathbf{X}_i, D_i(0) \neq D_i(1)]$  unobserved complier gains.

## Appendix: CM with Selection

Suppose  $Z_i$  is ignorable,  $D_i$  is not, so we have the following causal model.

Main problem, second-stage is not identified:

$$\begin{aligned}\mathbb{E}[Y_i | Z_i, D_i, \mathbf{X}_i] &= \alpha + \beta D_i + \gamma Z_i + \delta Z_i D_i + \varphi(\mathbf{X}_i) \\ &+ (1 - D_i) \mathbb{E}[U_{0,i} | D_i = 0, \mathbf{X}_i] \\ &+ \underbrace{D_i \mathbb{E}[U_{1,i} | D_i = 1, \mathbf{X}_i]}_{\text{Unobserved } D_i \text{ confounding.}}\end{aligned}$$

**Identification intuition:** Identify second-stage via MTE control function.

## Appendix: CM with Selection — Identification

Assume:

- ① Mediator monotonicity,  $\Pr(D_i(0) \leq D_i(1) \mid \mathbf{X}_i) = 1$   
 $\implies D_i(z') = \mathbb{1}\{U_i \leq \pi(z'; \mathbf{X}_i)\}, \text{ for } z' = 0, 1 \text{ (Vycatil 2002).}$
- ② Selection on mediator benefits,  $\text{Cov}(U_i, U_{0,i}), \text{Cov}(U_i, U_{1,i}) \neq 0$   
 $\implies$  First-stage take-up informs second-stage confounding.
- ③ There is an IV for the mediator,  $\mathbf{X}_i^{\text{IV}}$  among control variables  $\mathbf{X}_i$ .  
 $\implies \pi(Z_i; \mathbf{X}_i) = \Pr(D_i = 1 \mid Z_i, \mathbf{X}_i)$  is separately identified.

---

**Proposition:**

$$\begin{aligned} & \mathbb{E}[Y_i(z', 1) - Y_i(z', 0) \mid Z_i = z', \mathbf{X}_i, U_i = p'] \\ &= \beta + \delta z' + \mathbb{E}[U_{1,i} - U_{0,i} \mid \mathbf{X}_i, U_i = p'], \quad \text{for } p' \in (0, 1). \end{aligned}$$

## Appendix: CM with Selection — Identification

The marginal effect has corresponding Control Functions (CFs), describing unobserved selection-into- $D_i$ ,

$$\rho_0 \lambda_0(p') = \mathbb{E} [U_{0,i} \mid p' \leq U_i], \quad \rho_1 \lambda_1(p') = \mathbb{E} [U_{1,i} \mid U_i \leq p'] .$$

These CFs restore second-stage identification, by extrapolating from  $\mathbf{X}_i^{IV}$  compliers to  $D_i(Z_i)$  mediator compliers,

$$\begin{aligned} \mathbb{E} [Y_i \mid Z_i, D_i, \mathbf{X}_i] &= \alpha + \beta D_i + \gamma Z_i + \delta Z_i D_i + \varphi(\mathbf{X}_i) \\ &\quad + \underbrace{\rho_0 (1 - D_i) \lambda_0(\pi(Z_i; \mathbf{X}_i)) + \rho_1 D_i \lambda_1(\pi(Z_i; \mathbf{X}_i))}_{\text{CF adjustment.}} \end{aligned}$$

This adjusted second-stage re-identifies the ADE and AIE,

$$\text{ADE} = \mathbb{E} [\gamma + \delta D_i], \quad \text{AIE} = \mathbb{E} \left[ \bar{\pi} \left( \beta + \delta Z_i + \underbrace{(\rho_1 - \rho_0) \Gamma(\pi(0; \mathbf{X}_i), \pi(1; \mathbf{X}_i))}_{\text{Mediator compliers extrapolation.}} \right) \right]$$

## Appendix: CM with Selection — Estimation

Will explain how estimation works, with simulation evidence.

- ① Random treatment  $Z_i \sim \text{Binom}(0.5)$ , for  $n = 5,000$ .
- ②  $(U_{0,i}, U_{1,i}) \sim \text{BivariateNormal}(0, 0, \sigma_0, \sigma_1, \rho)$ , Costs  $C_i \sim N(0, 0.5)$ .

Roy **selection-into- $D_i$** , with constant partial effects + interaction term.

$$D_i(z') = \mathbb{1} \{C_i \leq Y_i(z', 1) - Y_i(z', 0)\},$$

$$Y_i(z', d') = (z' + d' + z'd') + U_{d'} \quad \text{for } z', d' = 0, 1.$$

Following the previous, these data have the following first and second-stage equations, where  $\mathbf{X}_i^{\text{IV}}$  is an additive cost IV:

$$D_i = \mathbb{1} \left\{ C_i - (U_{1,i} - U_{0,i}) \leq Z_i - \mathbf{X}_i^{\text{IV}} \right\}$$

$$Y_i = Z_i + D_i + Z_i D_i + (1 - D_i) U_{0,i} + D_i U_{1,i}.$$

$\implies$  unobserved confounding by BivariateNormal  $(U_{0,i}, U_{1,i})$ .

## Appendix: CM with Selection — Estimation

Errors are normal, so system is Heckman (1979) selection model.

CFs are the inverse Mills ratio, with  $\phi(\cdot)$  normal pdf and  $\Phi(\cdot)$  normal cdf,

$$\lambda_0(p') = \frac{\phi(-\Phi^{-1}(p'))}{\Phi(-\Phi^{-1}(p'))}, \quad \lambda_1(p') = \frac{\phi(\Phi^{-1}(p'))}{\Phi(\Phi^{-1}(p'))}, \quad \text{for } p' \in (0, 1).$$

---

### Parametric Estimation Recipe:

- ① Estimate first-stage  $\pi(Z_i; \mathbf{X}_i)$  with probit, including  $\mathbf{X}_i^{\text{IV}}$ .
  - ② Include  $\lambda_0, \lambda_1$  CFs in second-stage OLS estimation.
  - ③ Compose CM estimates from two-stage plug-in estimates.
- 

→ Same as conventional CM estimates (two-stages), with CFs added.

$$\widehat{\text{ADE}} = \mathbb{E} \left[ \widehat{\gamma} + \widehat{\delta} D_i \right], \quad \widehat{\text{AIE}} = \mathbb{E} \left[ \widehat{\pi} \left( \widehat{\beta} + \widehat{\delta} Z_i + \underbrace{(\widehat{\rho}_1 - \widehat{\rho}_0) \Gamma(\widehat{\pi}(0; \mathbf{X}_i), \widehat{\pi}(1; \mathbf{X}_i))}_{\text{Mediator compliers extrapolation.}} \right) \right]$$

## Appendix: CM with Selection — Estimation

If errors are not normal, then CFs do not have a known form, so semi-parametrically estimate them (e.g., splines).

$$\mathbb{E}[Y_i | Z_i, D_i = 0, \mathbf{X}_i] = \alpha + \gamma Z_i + \varphi(\mathbf{X}_i) + \rho_0 \lambda_0(\pi(Z_i; \mathbf{X}_i)),$$

$$\mathbb{E}[Y_i | Z_i, D_i = 1, \mathbf{X}_i] = (\alpha + \beta) + (\gamma + \delta) Z_i + \varphi(\mathbf{X}_i) + \rho_1 \lambda_1(\pi(Z_i; \mathbf{X}_i))$$

### Semi-parametric Estimation Recipe:

- 1 Estimate first-stage  $\pi(Z_i; \mathbf{X}_i)$ , including  $\mathbf{X}_i^{\text{IV}}$ .
- 2 Estimate second-stage separately for  $D_i = 0$  and  $D_i = 1$ , with regressors  $\lambda_0(p')$ ,  $\lambda_1(p')$ , semi-parametric in  $\hat{\pi}(Z_i; \mathbf{X}_i)$ .
- 3 Compose CM estimates from two-stage plug-in estimates.

→ Same as conventional CM estimates, with semi-parametric CFs. ▶ CFs.

$$\widehat{\text{ADE}} = \mathbb{E}[\hat{\gamma} + \hat{\delta} D_i], \quad \widehat{\text{AIE}} = \mathbb{E}\left[\hat{\pi}\left(\hat{\beta} + \hat{\delta} Z_i + (\hat{\rho}_1 - \hat{\rho}_0) \Gamma(\hat{\pi}(0; \mathbf{X}_i), \hat{\pi}(1; \mathbf{X}_i))\right)\right]$$
